

Kasi Mart Snowflake Project - Query Write-Up

Query 1: Detailed Order Information

This query provides a detailed view of each order by combining order, customer, and product information. It calculates the revenue for each order line by multiplying the quantity ordered by the product unit price. This is useful because it provides a complete view of individual transactions and forms the basis for analysing total revenue.

Query 2: Total Revenue per Customer

This query calculates the total revenue generated by each customer by summing the revenue from their orders. The results are grouped by customer and ordered from highest to lowest revenue. This is useful for identifying customers who contribute the most revenue to the business.

Query 3: Total Revenue per Product Category

This query calculates the total revenue generated by each product category. It combines order quantities with product prices and sums the resulting revenue for each category. This is useful for comparing the performance of different product categories and identifying which categories generate the most revenue.

Query 4: Top 5 Customers by Total Spend

This query calculates the total amount spent by each customer, orders the customers from highest to lowest spend, and returns only the top five customers. This is useful for identifying the highest-value customers and understanding which customers make the largest contribution to sales.
